In the second scenario we need to build Product B as an app, that interacts with the database, and stores and query the new values. Architecture Here the general architecture of the database: The first thing that we need is to create a schema (it is like a general structure of the database, in the case of SQL, but with a more object-oriented language). On the other hand, we also need to build the app of the database (is like the application that uses the database), and the other application (is like Product B). Step 1: Create a schema Open Visual Studio and create a new solution and select the Data Package template: In the next step, we have to add
